Abstract

The conditional gradient method is a long-studied first-order optimization method for smooth convex optimization. Its main appeal is the low computational complexity: the conditional gradient method requires only a single linear optimization operation per iteration. In contrast, other first-order methods require a projection computation every iteration, which is the computational bottleneck for many large scale optimization tasks. The drawback of the conditional gradient method is its relatively slow convergence rate.

In this work we present a new conditional gradient algorithm for smooth and strongly convex optimization over polyhedral sets with a linear convergence rate - an exponential improvement over previous results.

We extend the algorithm to the online and stochastic settings, and give the first conditional gradient algorithm that attains optimal regret bounds for both arbitrary convex losses and strongly convex losses. Our online and stochastic algorithms require a single linear optimization step over the domain per iteration.

1 Introduction

First-order optimization methods, such as gradient-descent methods [19, 16, 17] and conditional-gradient methods [6, 5, 4, 8, 13], are often the method of choice for coping with very large scale optimization tasks. While theoretically
attaining inferior convergence rate compared to other efficient optimization algorithms, e.g. interior point methods [18], modern optimization problems are often so large that using second-order information or other super-linear operations becomes practically infeasible.

The computational bottleneck of gradient descent methods is usually the computation of orthogonal projections onto the convex domain. This is also the case with proximal methods [17].

A well-known remedy for the latter computational problem is the conditional gradient method, also known as the Frank-Wolfe method. Conditional-gradient methods are suitable for smooth optimization and do not rely on computing projections, instead each iteration is comprised of optimizing a single linear objective over the convex domain. The latter task is many times accomplishable using a very efficient combinatorial algorithm for many domains of interest.

Our first contribution in this paper is the design of a new conditional-gradient-based algorithm for smooth and strongly convex optimization. Unlike previous methods, our new algorithm attains a linear rate of convergence over polytopes, thus running in polynomial time for many combinatorial optimization problems.

Using this new linearly converging algorithm, we are able to design new algorithms for stochastic and online convex optimization. Using the conditional gradient method for solving stochastic and online problems is of utmost importance in machine learning, due to the very large scale optimization problems that arise. Recently, a conditional gradient algorithm for stochastic and online optimization was given in [12], though its rate is sub-optimal. We give the first optimal-rate CG algorithms for these problems, thereby resolving the question of [12]. Our results are summarized in the

Table 1: Comparison of conditional gradient methods for optimization over polytopes in various settings. In the offline and stochastic settings we give the convergence rates, omitting constants. In the online setting we give the order of the regret after $T$ rounds.
1.1 Related Work

**Offline optimization**  Conditional gradient methods for offline minimization of convex and smooth functions date back to the work of Frank and Wolfe [6]. More recent works of Clarkson [4] and Hazan [8] consider the conditional gradient method for the cases of optimization over the simplex and semidefinite cone respectively. Albeit its relatively slow convergence rates - additive error of the order $1/t$ after $t$, the benefit of the method is two folded: i) its computational simplicity - each iteration is comprised of optimizing a linear objective over the set and ii) it is known to produce sparse solutions (for the simplex this mean only a few non zeros entries, for the semidefinite cone this means that the solution has low rank). The results of [4, 8] are generalized in [13], showing that the same rate of convergence is achievable for arbitrary convex and compact sets as long as an oracle for optimizing a linear objective over the set is available. The convergence rate $1/t$ is also optimal for this method without further assumptions, as shown in [4, 8, 13].

For the special problem of solving convex linear systems - finding a point in the intersection of an affine set with a compact convex set, [2] gives a conditional gradient algorithm with linear convergence, but a slater condition assumption is needed, that is they assume that a solution exists that is far enough from the boundary of the convex set. The recent work of [1] uses the linear convergence result of [2] for the problem of learning in intractable markov random fields models.

For the case in which the the objective function is smooth and strongly convex, an extension of the conditional-gradient algorithm with linear convergence rate was presented in [15], however their algorithms require to solve a regularized linear problem on each iteration which is computationally equivalent to computing projections. In case the convex set is a polytope, [7] has shown that the algorithm of [6] converges in linear rate assuming that the optimal point in the polytope is bounded away from the boundary. The convergence rate is proportional to a quadratic of the distance of the optimal point from the boundary. In our work we do not require the latter assumption and the convergence rate does not depend on the optimal solution.

**Online and Stochastic Optimization**  The two closest works to ours are [14] and [12], in both no projections are used, and the only optimization carried out by the algorithms on each iteration is minimizing a linear objective over the decision set. [14] gives a random algorithm for the online setting in the special case in which all loss function are linear. In this setting their
algorithm achieves regret of $O(\sqrt{T})$ which is optimal. On iteration $t$ their algorithm plays a point in the decision set that minimizes the cumulative loss on all previous iterations plus a random noise. The work of [12] introduces algorithms for stochastic and online optimization which are based on ideas similar to ours - using the conditional gradient update step and the convergence of the RTFL algorithm [9]. For stochastic optimization, in the case that all loss functions are smooth they achieve an optimal convergence rate of $1/\sqrt{T}$, however for non-smooth stochastic optimization they only get convergence rate of $T^{-1/4}$ and for the full adversarial setting of online convex optimization they get suboptimal regret that scales like $T^{3/4}$.

2 Preliminaries

Given two vectors $x, y$ we write $x \geq y$ if every entry of $x$ is greater or equal to the corresponding entry in $y$. We denote $\mathbb{B}_r(x)$ the euclidean ball of radius $r$ centred at $x$. We denote by $\|x\|$ the $l_2$ norm of the vector $x$ and by $\|A\|$ the spectral norm of the matrix $A$, that is $\|A\| = \max_{x \in \mathbb{B}} \|Ax\|$. Given a matrix $A$ we denote by $A(i)$ the vector that corresponds to the $i$th row of $A$.

Definition 1. We say that a function $f : \mathbb{R}^n \rightarrow \mathbb{R}$ is Lipschitz with parameter $L$ over the set $\mathcal{K} \subset \mathbb{R}^n$ if for all $x, y \in \mathcal{K}$ it holds that,

$$|f(x) - f(y)| \leq L\|x - y\|$$

Definition 2. We say that a function $f : \mathbb{R}^n \rightarrow \mathbb{R}$ is $\beta$-smooth over the set $\mathcal{K}$ if for all $x, y \in \mathcal{K}$ it holds that,

$$f(y) \leq f(x) + \nabla f(x)^\top (y - x) + \beta\|x - y\|^2$$

Definition 3. We say that a function $f : \mathbb{R}^n \rightarrow \mathbb{R}$ is $\sigma$-strongly convex over the set $\mathcal{K}$ if for all $x, y \in \mathcal{K}$ it holds that,

$$f(y) \geq f(x) + \nabla f(x)^\top (y - x) + \sigma\|x - y\|^2$$

The above definition together with first order optimality conditions imply that for a $\sigma$-strongly convex $f$, if $x^* = \arg \min_{x \in \mathcal{K}} f(x)$, then for all $x \in \mathcal{K}$

$$f(x) - f(x^*) \geq \sigma\|x - x^*\|$$

Given a polytope $\mathcal{P} = \{x \in \mathbb{R}^n | A_1x = b_1, A_2x \leq b_2\}$, $A_2$ is $m \times n$, let $\mathcal{V}$ denote the set of vertices of $\mathcal{P}$ and let $N = |\mathcal{V}|$. We assume that $\mathcal{P}$ is bounded and we denote $D(\mathcal{P}) = \max_{x, y \in \mathcal{P}} \|x - y\|$. 

4
We denote $\xi(P) = \min_{v \in V} \min \{b_2(j) - A_2(j)v : j \in [m], A_2(j)v < b_2(j)\}$. Let $r(A_2)$ denote the row rank of the matrix $A_2$. Let $A(P)$ denote the set of all $r(A_2) \times n$ matrices whose rows are linearly independent vectors chosen from the rows of $A_2$ and denote $\psi(P) = \max_{M \in A(P)} \|M\|_2$. Finally denote $\mu(P) = \frac{\psi(P)D(P)}{\xi(P)}$.

Henceforth we shall use the shorthand notation of $D, \xi, \psi, \mu$ when the polytope at hand is clear from the context.

Throughout this work we will assume that we have access to an oracle for minimizing a linear objective over $P$. That is we are given a procedure $O_P : \mathcal{V} \rightarrow \mathbb{R}$ such that for all $c \in \mathbb{R}^n$, $O_P(c) \in \arg \min_{v \in \mathcal{V}} c^\top v$.

### 2.1 The Conditional Gradient Method and Local Linear Oracles

The conditional gradient method is a simple algorithm for minimizing a smooth convex function $f$ over a convex set $P$ - which in this work we assume to be a polytope. The appeal of the method is that it is a first order interior point method - the iterates always lie inside the convex set and thus no projections are needed and the update step on each iteration simply requires to minimize a linear objective over the set. The basic algorithm is given below.

**Algorithm 1 Conditional Gradient**

1. Let $x_1$ be an arbitrary point in $P$.
2. for $t = 1, \ldots$ do
3. $p_t \leftarrow O_P(\nabla f(x_t))$.
4. $x_{t+1} \leftarrow x_t + \alpha_t(p_t - x_t)$ for $\alpha_t \in (0, 1)$.
5. end for

Let $x^* = \arg \min_{x \in K} f(x)$. The proof of convergence of algorithm [1] is due to the following simple observation.

\[
\begin{align*}
    f(x_{t+1}) - f(x^*) &
    
    = f(x_t + \alpha_t(p_t - x_t)) - f(x^*) 
    
    \leq f(x_t) - f(x^*) + \alpha_t(p_t - x_t)^\top \nabla f(x_t) + \alpha_t^2 \beta \|p_t - x_t\|^2 
    
    \leq f(x_t) - f(x^*) + \alpha_t(x^* - x_t)^\top \nabla f(x_t) + \alpha_t^2 \beta \|p_t - x_t\|^2 
    
    \leq f(x_t) - f(x^*) + \alpha_t(f(x^*) - f(x_t)) + \alpha_t^2 \beta \|p_t - x_t\|^2 
    
    \leq (1 - \alpha_t)(f(x_t) - f(x^*)) + \alpha_t^2 \beta D^2
\end{align*}
\]

The relatively slow convergence of the conditional gradient algorithm is due to the term $\|p_t - x_t\|$ in the above analysis, that may remain as large as the
diameter of $\mathcal{P}$ while the term $f(x_t) - f(x^*)$ keeps on shrinking, that forces us to choose values of $\alpha_t$ that decrease like $\frac{1}{t}$ [4, 8, 13].

Notice that if $f$ is $\sigma$-strongly convex for some $\sigma > 0$ then knowing that for some iteration $t$ it holds that $f(x_t) - f(x^*) \leq \epsilon$ implies that $\|x_t - x^*\|^2 \leq \frac{\epsilon}{\sigma}$.

Thus when choosing $p_t$, denoting $r = \sqrt{\epsilon/\sigma}$, it is enough to consider points that lie in the intersection set $\mathcal{P} \cap B_r(x_t)$. In this case the term $\|p_t - x_t\|^2$ will be of the same magnitude as $f(x_t) - f(x^*)$ (or even smaller) and as observable in (1), linear convergence may be attainable. However solving the problem $\min_{p \in \mathcal{P} \cap B_r(x_t)} p^\top \nabla f(x_t)$ is much more difficult than solving the original linear problem $\min_{p \in \mathcal{P}} p^\top \nabla f(x_t)$ and is not straight-forward solvable using linear optimization over the original set alone.

To overcome the problem of solving the linear problem in the intersection $\mathcal{P} \cap B_r(x_t)$ we introduce the following definition which is a primary ingredient of our work.

**Definition 4 (Local Linear Oracle).** We say that a procedure $A(x, r, c)$, $x \in \mathcal{P}$, $r \in \mathbb{R}^+$, $c \in \mathbb{R}^n$ is a Local Linear Oracle for the polytope $\mathcal{P}$ with parameter $\rho$, if $A(x, r, c)$ returns a point $p \in \mathcal{P}$ such that:

1. $\forall y \in B(x, r) \cap \mathcal{P}$ it holds that $c^\top y \geq c^\top p$.
2. $\|x - p\| \leq \rho \cdot r$.

The local linear oracle (LLO) relaxes the problem $\min_{p \in \mathcal{P} \cap B_r(x_t)} p^\top \nabla f(x_t)$ by solving the linear problem on a larger set, but one that still has a diameter that is not much larger than $\sqrt{f(x_t) - f(x^*)}$. Our main contribution is showing that for a polytope $\mathcal{P}$ a local linear oracle can be constructed such that the parameter $\rho$ depends only on dimension $n$ and the quantity $\mu(\mathcal{P})$. Moreover the construction requires only a single call to the oracle $O_\mathcal{P}$.

### 2.2 Online and Stochastic Convex Optimization

In the problem of online convex optimization (OCO) [20, 11, 9], a decision maker is iteratively required to choose a point $x_t \in \mathcal{K}$ where $\mathcal{K}$ is a convex set. After choosing the point $x_t$, a convex loss function $f_t(x)$ is revealed and the decision maker incurs loss $f_t(x_t)$. The emphasis in this model is that the loss function at time $t$ may be chosen completely arbitrarily and even in an adversarial manner given the current and past decisions of the decision maker. The goal of the decision maker it to minimize his overall loss and performance is measured in terms of regret - the difference between the overall loss of the decision maker and that of the best fixed point in $\mathcal{K}$ in
hindsight. Formally the regret after $T$ rounds is given by

$$\sum_{t=1}^{T} f_t(x_t) - \min_{x \in \mathcal{K}} \sum_{t=1}^{T} f_t(x)$$

The main challenge in this setting is to design algorithms with regret bounds that are sublinear in the number of rounds - $T$. For general convex losses the optimal regret bound attainable scales like $\sqrt{T}$ [3]. In the case that all loss function are strongly convex the optimal regret bound attainable scales like $\log(T)$ [11].

A simple algorithm that attains regret of $O(\sqrt{T})$ for general convex losses is known as the Regularized Follows The Leader algorithm (RTFL) [9]. On time $t$ the algorithm predicts according to the following rule.

$$x_t \leftarrow \min_{x \in \mathcal{K}} \left\{ \eta \sum_{t=1}^{t-1} \nabla f_{t'}(x_{t'}) \top x + \mathcal{R}(x) \right\}$$ (2)

Where $\eta$ is a parameter known as the learning rate and $\mathcal{R}$ is a strongly convex function known as the regularization. From an offline optimization point of view, achieving low regret is thus equivalent to solving a strongly-convex quadratic minimization problem on every iteration. We will show how to attain low regret by using only a linear optimization oracle using the ideas from subsection 2.2.

### 2.2.1 Stochastic Optimization

In stochastic optimization the goal is to minimize a convex function $F(x)$ over the convex set $\mathcal{P}$ where we assume that there exists a distribution $\mathcal{D}$ over a set of functions such that $F = \mathbb{E}_{f \sim \mathcal{D}}[f]$. In this setting we don’t have direct access to the function $F$, instead we assume to have a random oracle for $F$ that we can query, which returns a function $f$ that is sampled according to the distribution $\mathcal{D}$ independently of previous samples. Thus if the oracle returns a function $f$ it holds that $\mathbb{E}[f(x)] = F(x)$ for all $x \in \mathcal{P}$.

The general setting of online convex optimization is strictly harder than that of stochastic optimization, in the sense that stochastic optimization can be simulated in the setting of online convex optimization - on each iteration $t$ the loss function revealed $f_t$ is produced by a query to the oracle of $F$. In this case denote by $\mathcal{R}_T$ the regret of an algorithm for online convex optimization after $T$ iterations. That is,

$$\sum_{t=1}^{T} f_t(x_t) - \min_{x \in \mathcal{K}} \sum_{t=1}^{T} f_t(x) = \mathcal{R}_T$$
Denoting \( x^* = \operatorname{arg\,min}_{x \in \mathcal{P}} F(x) \) we thus in particular have,
\[
\sum_{t=1}^{T} f_t(x_t) - \sum_{t=1}^{T} f_t(x^*) \leq \mathcal{R}_T
\]
Taking expectation over the randomness of the oracle for \( F \) and dividing by \( T \) we have,
\[
\frac{1}{T} \sum_{t=1}^{T} F(x_t) - F(x^*) \leq \frac{\mathcal{R}_T}{T}
\]
Denoting \( \bar{x} = \frac{1}{T} \sum_{t=1}^{T} x_t \) we have by convexity of \( F \) that,
\[
F(\bar{x}) - F(x^*) \leq \frac{\mathcal{R}_T}{T}
\]
Thus the same regret rates that are attainable for online convex optimization hold as convergence rates, or sample complexity, for stochastic optimization.

3 Our Results

In all of our results we assume that we perform optimization (either offline or online) over a polytope \( \mathcal{P} \) and that we have access to an oracle \( \mathcal{O}_\mathcal{P} \) that given a linear objective \( c \in \mathbb{R}^n \) returns a vertex of \( \mathcal{P} \) - \( v \in \mathcal{V} \) that minimizes \( c \) over \( \mathcal{P} \).

**Offline Optimization**  Given a \( \beta \)-smooth, \( \sigma \)-strongly convex function \( f(x) \) we present an iterative algorithm that after \( t \) iterations returns a point \( x_{t+1} \in \mathcal{P} \) such that
\[
f(x_{t+1}) - f(x^*) \leq C \exp \left( -\frac{\sigma}{4\beta \mu^2} t \right)
\]
where \( x^* = \arg\min_{x \in \mathcal{P}} f(x) \) and \( C = f(x_t) - f(x^*) \). The algorithm makes a total of \( t \) calls to the linear oracle of \( \mathcal{P} \).

**Online and Stochastic Optimization**  We present an algorithm for online convex optimization such that

1. For arbitrary convex loss functions the regret after \( T \) rounds is
\[
\sum_{t=1}^{T} f_t(x_t) - \min_{x^* \in \mathcal{P}} \sum_{t=1}^{T} f_t(x^*) = O \left( GD\sqrt{n} \mu \sqrt{T} \right)
\]
2. If all loss functions are $H$-strongly convex then the regret after $T$ rounds is
\[
\sum_{t=1}^{T} f_t(x_t) - \min_{x^*} \sum_{t=1}^{T} f_t(x^*) = O \left( \frac{(G + HD)\eta \mu^2}{H} \log(T) \right)
\]

The algorithm performs a single call to the linear oracle of $P$ per iteration.

As discussed in subsection 2.2.1 online regret bounds could be directly translated to convergence rates for stochastic optimization.

4 A New Linearly Convergent Algorithm for Offline Optimization

In this section we present and analyse an algorithm for the following offline optimization problem
\[
\min_{x \in \mathcal{P}} f(x) \tag{3}
\]
where we assume that $f$ is $\beta$-smooth and $\sigma$-strongly convex and $\mathcal{P}$ is a polytope. We assume that we have a LLO oracle for $\mathcal{P} - \mathcal{A}(x, r, c)$. In section 5 we show that given an oracle for linear minimization over $\mathcal{P}$, such a LLO oracle can be constructed.

Our algorithm for (3) is given below,

**Algorithm 2**

1: Input: $\mathcal{A}(x, r, c)$ - LLO with parameter $\rho$.
2: Let $x_1$ be an arbitrary point in $\mathcal{V}$ and let $C \geq f(x_1) - f(x^*)$.
3: Let $\alpha = \frac{\sigma}{2\beta \rho}$. 
4: for $t = 1...$ do 
5: \hspace{1em} $r_t \leftarrow \min \left\{ \sqrt{\frac{C}{\sigma}} e^{-\alpha^2(t-1)}, D \right\}$. 
6: \hspace{1em} $p_t \leftarrow \mathcal{A}(x_t, r_t, \nabla f(x_t))$. 
7: \hspace{1em} $x_{t+1} \leftarrow x_t + \alpha (p_t - x_t)$. 
8: end for

**Theorem 1.** After $t \geq 1$ iterations algorithm 2 has made $t$ calls to the linear oracle $\mathcal{O}_\mathcal{P}$ and the point $x_{t+1} \in \mathcal{P}$ satisfies
\[
f(x_{t+1}) - f(x^*) \leq C \exp \left( -\frac{\sigma}{4\beta \eta \mu^2} t \right)
\]
where $x^* = \arg\min_{x \in \mathcal{P}} f(x)$ and $C = f(x_1) - f(x^*)$. 

9
We now turn to analyse the convergence rate of algorithm. The following lemma is of general interest and will be used also in the section on online optimization.

**Lemma 1.** Assume that $f(x)$ is $\beta$-smooth. Let $x^* = \text{arg min}_{x \in \mathcal{P}} f(x)$ and assume that on iteration $t$ it holds that $\|x_t - x^*\| \leq r_t$. Then for every $\alpha \in (0,1)$ it holds that,

$$f(x_{t+1}) - f(x^*) \leq (1 - \alpha)(f(x_t) - f(x^*)) + \beta \alpha^2 \min \{\rho^2 r_t^2, D^2\}$$

**Proof.** By the $\beta$-smoothness of $f(x)$ and the update step of algorithm we have,

$$f(x_{t+1}) = f(x_t + \alpha (p_t - x_t)) \leq f(x_t) + \alpha \nabla f(x_t)^\top (p_t - x_t) + \beta \alpha^2 \|p_t - x_t\|^2$$

Since $\|x_t - x^*\| \leq r_t$, by the definition of the oracle $\mathcal{A}$ it holds that i) $p_t^\top \nabla f(x_t) \leq x^*^\top \nabla F_t(x_t)$ and ii) $\|x_t - p_t\| \leq \min \{\rho r_t, D\}$. Thus we have that,

$$f(x_{t+1}) \leq f(x_t) + \alpha \nabla f(x_t)^\top (x^* - x_t) + \beta \alpha^2 \min \{\rho^2 r_t^2, D^2\}$$

Using the convexity of $f(x)$ and subtracting $f(x^*)$ from both sides we have,

$$f(x_{t+1}) - f(x^*) \leq (1 - \alpha)(f(x_t) - f(x^*)) + \beta \alpha^2 \min \{\rho^2 r_t^2, D^2\}$$

\[\square\]

**Lemma 2.** Let $\alpha$ be as in algorithm. Denote $h_t = f(x^*) - f(x_t)$ and let $C \geq h_1$. Then

$$h_t \leq Ce^{-\frac{\alpha}{4\rho^2}(t-1)} \quad \forall t \geq 1$$

**Proof.** The proof is by a simple induction. For $t = 1$ we have that $h_1 = f(x^*) - f(x_1) \leq C$.

Now assume that the theorem holds for $t \geq 1$. This implies via the strong convexity of $f(x)$ that

$$\|x_t - x^*\|^2 \leq \frac{1}{\sigma}(f(x^*) - f(x_t)) = \frac{1}{\sigma}h_t \leq \frac{C}{\sigma}e^{-\frac{\alpha}{4\rho^2}(t-1)}$$

Setting $r_t$ such that $r_t^2 = \frac{C}{\sigma}e^{-\frac{\alpha}{4\rho^2}(t-1)}$, we have that $x^* \in P \cap \mathbb{B}_{r_t}(x_t)$. Applying lemma with respect to $x_t$ and by induction we get,

$$h_{t+1} \leq (1 - \alpha)Ce^{-\frac{\alpha}{4\rho^2}(t-1)} + \frac{\alpha^2 \beta \rho^2}{\sigma}Ce^{-\frac{\alpha}{4\rho^2}(t-1)}$$

$$\leq Ce^{-\frac{\alpha}{4\rho^2}(t-1)}(1 - \alpha + \frac{\alpha^2 \beta \rho^2}{\sigma})$$
By plugging the value of $\alpha$ and using $(1 - x) \leq e^{-x}$ we have
\[ h_{t+1} \leq C e^{-\frac{\sigma^2}{4\rho^2}}. \]

We can now prove theorem 1.

**Proof.** In lemma 5 we prove that a LLO oracle with parameter $\rho = \sqrt{n}\mu$ and in lemma 6 we shows that this construction requires a single call to the oracle $O_P$. The convergence results thus follows from 2.

5 Constructing a Local Linear Oracle

In this subsection we show how to construct an algorithm for the procedure $A(x, r, c)$ given only an oracle that minimizes a linear objective over the polytope $P$.

The algorithm for the local linear oracle is given below. Note that the algorithm assumes that the input point $x$ is given in the form of a convex combination of vertices of the polytope. Later on we show that maintaining such a decomposition of the input point $x$ is easy.

**Algorithm 3**

1: Input: a point $x \in P$ such that $x = \sum_{i=1}^{k} \lambda_i v_i$, $\lambda_i > 0$, $\sum_{i=1}^{k} \lambda_i = 1$, $v_i \in V$, radius $r > 0$, linear objective $c \in \mathbb{R}^n$.  
2: $\Delta \leftarrow \min \{ \sqrt{n} \xi r, 1 \}$.  
3: $\forall i \in [k]: l_i \leftarrow c^T v_i$.  
4: Let $i_1, \ldots, i_k$ be a permutation over $[k]$ such that $l_{i_1} \geq l_{i_2} \geq \ldots l_{i_k}$.  
5: for $j = 1 \ldots k$ do  
6: $\lambda'_{i_j} \leftarrow \max \{0, \lambda_{i_j} - \Delta\}$.  
7: $\Delta \leftarrow \Delta - (\lambda_{i_j} - \lambda'_{i_j})$.  
8: end for  
9: $v \leftarrow O_P(c)$.  
10: return $p \leftarrow \sum_{i=1}^{k} \lambda'_{i_j} v_i + (1 - \sum_{i=1}^{k} \lambda'_{i_j}) v$.

**Lemma 3.** Let $x \in P$ the input to algorithm 3 and let $y \in P$. Write $y = \sum_{i=1}^{k} (\lambda_i - \Delta_i) v_i + (\sum_{i=1}^{k} \Delta_i) z$ for some $\Delta_i \in [0, \lambda_i]$ and $z \in P$ such that the sum $\sum_{i=1}^{k} \Delta_i$ is minimized. Then $\forall i \in [k]$ there exists an index $j \in [m]$ such that $A_2(j)v_i < b_2(j)$ and $A_2(j)z = b_2(j)$. 

11
Proof. Denote $\Delta = \sum_{i=1}^{k} \Delta_i$. Assume the lemma is false and let $i' \in [k]$ such that $\forall j \in [m]$ it holds that if $A_2(j)v_{i'} < b_2(j)$ then $A_2(j)z < b_2(j)$. Given $j \in [m]$ we consider two cases. If $A_2(j)v_{i'} = b_2(j)$ then for any $\gamma \in (0, 1]$ it holds that $A_2(j)(z - \gamma v_{i'}) \leq b_2(j) - \gamma b_2(j) = (1 - \gamma) b_2(j)$

If $A_2(j)v_{i'} < b_2(j)$ then by the assumption $A_2(j)z < b_2(j)$ and there exists scalars $\epsilon_j, \delta_j > 0$ such that $A_2(j)v_{i'} = b_2(j) - \delta_j$ and $A_2(j)z = b_2(j) - \epsilon_j$. Now given a scalar $\gamma > 0$ it holds that $A_2(j)(z - \gamma v_{i'}) = b_2(j) - \epsilon_j - \gamma (b_2(j) - \delta_j) = (1 - \gamma) b_2(j) - (\epsilon_j - \gamma \delta_j)$. Choosing $\gamma \leq \frac{\epsilon_j}{\delta_j}$ we get that $A_2(j)(z - \gamma v_{i'}) \leq (1 - \gamma) b_2(j)$.

Combining the two cases above we conclude that for all $\gamma \leq \min\{1, \min_{j \in [m]} \{\frac{\epsilon_j}{\delta_j}\}\}$ it holds that $A_2(z - \gamma v_{i'}) \leq (1 - \gamma)b_2$. Since it also holds that $A_1(z - \gamma v_{i'}) = (1 - \gamma)b_1$ we have that $z - \gamma v_{i'} \in (1 - \gamma)\mathcal{P}$.

Thus in particular by choosing $\gamma$ such that $\gamma \leq \frac{\Delta_{i'}}{\Delta}$, there exists $w \in \mathcal{P}$ such that $z = (1 - \gamma)w + \gamma v_{i'}$ and,

$$y = \sum_{i=1}^{k} (\lambda_i - \Delta_i)v_i + \Delta z$$

$$= \sum_{i=1}^{k} (\lambda_i - \Delta_i)v_i + \Delta((1 - \gamma)w + \gamma v_{i'})$$

$$= \left( \sum_{i=1, i \neq i'}^{k} (\lambda_i - \Delta_i)v_i + (\lambda_{i'} - (\Delta_{i'} - \gamma \Delta) - \gamma \Delta)v_{i'} \right) + \Delta(1 - \gamma)w + \gamma \Delta v_{i'}$$

$$= \left( \sum_{i=1, i \neq i'}^{k} (\lambda_i - \Delta_i)v_i + (\lambda_{i'} - (\Delta_{i'} - \gamma \Delta)v_{i'} \right) + \Delta(1 - \gamma)w$$

Thus by defining $\forall i \in [k], i \neq i', \hat{\Delta}_i = \Delta_i$ and $\hat{\Delta}_{i'} = \Delta_{i'} - \gamma \Delta$ we have that $y = \sum_{i=1}^{k} (\lambda_i - \hat{\Delta}_i)v_i + (\sum_{i=1}^{k} \hat{\Delta}_i)w$ with $\sum_{i=1}^{k} \hat{\Delta}_i = (1 - \gamma) \sum_{i=1}^{k} \Delta_i$ which contradicts the minimality of $\sum_{i=1}^{k} \Delta_i$. \hfill $\square$

**Claim 1.** Let $z \in \mathcal{P}$ and denote $C(z) = \{i \in [m] : A_2(i)z = b_2(i)\}$ and let $C_0(z) \subseteq C(z)$ be such that the set $\{A_2(i)\}_{i \in C_0(z)}$ is a basis for the set $\{A_2(i)\}_{i \in C(z)}$. Then given $y \in \mathcal{P}$, if there exists $i \in C(z)$ such that $A_2(i)y < b_2(i)$ then there exists $i_0 \in C_0(z)$ such that $A_2(i_0)y < b_2(i_0)$.

**Proof.** Assume by way of contradiction that there exists $y \in \mathcal{P}$ and $i \in C(z)$ such that $A_2(i)y < b_2(i)$ and for any $j \in C_0(z)$ it holds that $A_2(j)y = b_2(j)$.

Since $A_2(i)$ is a linear combination of vectors from $\{A_2(i)\}_{i \in C_0(z)}$ it follows that the linear system $A_2(j)x = b_2(j), j \in C_0(z) \cup \{i\}$ has no solution which is a contradiction to the assumption that $A_2(i)z = b_2(i)$ $\forall i \in C(z)$. \hfill $\square$
Lemma 4. Let $x \in \mathcal{P}$ the input to algorithm 3 and let $y \in \mathcal{P}$ such that $\|x - y\| \leq r$. Write $y = \sum_{i=1}^{k} (\lambda_i - \Delta_i) v_i + (\sum_{i=1}^{k} \Delta_i) z$ for some $\Delta_i \in [0, \lambda_i]$ and $z \in \mathcal{P}$ such that the sum $\sum_{i=1}^{k} \Delta_i$ is minimized. Then $\sum_{i=1}^{k} \Delta_i \leq \sqrt{n\psi} \cdot r$.

Proof. Denote $C(z) = \{j \in [m] : A_2(j) z = b_2(j)\}$ and let $C_0(z) \subseteq C(z)$ such that the set of vectors $\{A_2(i)\}_{i \in C_0(z)}$ is a basis for the set $\{A_2(i)\}_{i \in C(z)}$. Denote $A_{2,z} \in \mathbb{R}^{|C_0(z)| \times n}$ the matrix $A_2$ after deleting every row $i \notin C_0(z)$ and recall that by definition $\|A_{2,z}\| \leq \psi$. Then it holds that,

$$
\|x - y\|^2 = \| \sum_{i=1}^{k} \Delta_i (v_i - z) \|^2 \geq \frac{1}{\|A_{2,z}\|^2} \| A_{2,z} \left( \sum_{i=1}^{k} \Delta_i (v_i - z) \right) \|^2
$$

$$
\geq \frac{1}{\psi^2} \| \sum_{i=1}^{k} \Delta_i A_{2,z} (v_i - z) \|^2 = \frac{1}{\psi^2} \sum_{j \in C_0(z)} \left( \sum_{i=1}^{k} \Delta_i (A_2(j) v_i - b_2(j)) \right)^2
$$

Note that $|C_0(z)| \leq n$ and that for any vector $x \in \mathbb{R}^{|C_0(z)|}$ it holds that $\|x\| \geq \frac{1}{\sqrt{|C_0(z)|}} \|x\|_1$. Thus we have that,

$$
\|x - y\|^2 \geq \frac{1}{n\psi^2} \left( \sum_{j \in C_0(z)} \left( \sum_{i=1}^{k} \Delta_i (A_2(j) v_i - b_2(j)) \right) \right)^2
$$

$$
= \frac{1}{n\psi^2} \left( \sum_{j \in C_0(z)} \sum_{i=1}^{k} \Delta_i (b_2(j) - A_2(j) v_i) \right)^2
$$

Combining lemma 3 and claim 5 we have that for all $i \in [k]$ such that $\Delta_i > 0$ there exists $j \in C_0(z)$ such that $A_2(j) v_i \leq b_2(j) - \xi$. Hence,

$$
\|x - y\|^2 \geq \frac{1}{n\psi^2} \left( \sum_{i=1}^{k} \Delta_i \xi \right)^2 = \frac{\xi^2}{n\psi^2} \left( \sum_{i=1}^{k} \Delta_i \right)^2
$$

Since $\|x - y\|^2 \leq r^2$ we conclude that $\sum_{i=1}^{k} \Delta_i \leq \frac{r}{\xi} \sqrt{n\psi} \cdot r$.

The following lemma establishes that algorithm 3 is a local linear oracle for $\mathcal{P}$ with parameter $\rho = \sqrt{n} \mu$.

Lemma 5. Assume that the input to algorithm 3 is $x = \sum_{i=1}^{k} \lambda_i v_i$ such that $\forall i \in [k], \lambda_i > 0, v_i \in \mathcal{V}$ and $\sum_{i=1}^{k} \lambda_i = 1$. Let $p$ be the point returned by algorithm 3. Then the following conditions holds:

1. $p \in \mathcal{P}$. 

13
2. $\|x - p\| \leq \sqrt{n \mu r}$.

3. $\forall y \in \mathbb{B}_r(x) \cap \mathcal{P}$ it holds that $c^\top y \geq c^\top p$.

Proof. Condition 1. holds since $p$ is given as convex combination of points in $\mathcal{V}$.

For condition 2. note that,

\[
\|x - p\| = \left\| \sum_{i=1}^k (\lambda_i - \lambda'_i)v_i - \left(1 - \sum_{i=1}^k \lambda'_i\right)v \right\|
\]

\[
= \left\| \sum_{i=1}^k (\lambda_i - \lambda'_i)v_i - \sum_{i=1}^k (\lambda_i - \lambda'_i)v \right\|
\]

\[
= \left\| \sum_{i=1}^k (\lambda_i - \lambda'_i)(v_i - v) \right\| \leq \sum_{i=1}^k (\lambda_i - \lambda'_i)\|v_i - v\|
\]

where the last inequality is due to the triangle inequality.

According to algorithm 3 it holds that $\sum_{i=1}^k (\lambda_i - \lambda'_i) \leq \sqrt{\nicefrac{\psi}{\xi}} r$ and thus $\|x - p\| \leq \frac{\sqrt{\psi r}}{\xi} = \sqrt{n \mu r}$.

Finally, for condition 3, let $y \in \mathbb{B}_r(x) \cap \mathcal{P}$. From lemma 4 we can write $y = \sum_{i=1}^k (\lambda_i - \Delta_i)v_i + \left(\sum_{i=1}^k \Delta_i\right)z$ such that $\Delta_i \in [0, \lambda_i]$, $z \in \mathcal{P}$ and $\sum_{i=1}^k \Delta_i = \min\{\sqrt{\frac{\psi}{\xi}} r, 1\}$. Thus,

\[
c^\top y = \sum_{i=1}^k (\lambda_i - \Delta_i)c^\top v_i + \left(\sum_{i=1}^k \lambda'_i\right)c^\top z
\]

\[
= \sum_{i=1}^k (\lambda_i - \Delta_i)l_i + \left(\sum_{i=1}^k \Delta_i\right)c^\top z
\]

\[
\geq \sum_{i=1}^k (\lambda_i - \Delta_i)l_i + \left(\sum_{i=1}^k \Delta_i\right)c^\top v
\]

\[
= \sum_{j=1}^k (\lambda_{i_j} - \Delta_{i_j})l_{i_j} + \left(\sum_{i=1}^k \Delta_i\right)c^\top v
\]

Since algorithm 3 reduces the weights of the vertices $v_i$ according to a decreasing order of $l_i$ we have that $\sum_{j=1}^k (\lambda_{i_j} - \Delta_{i_j})l_{i_j} \geq \sum_{j=1}^k \lambda'_{i_j} l_{i_j}$. Thus we conclude that $c^\top y \geq \sum_{j=1}^k \lambda'_{i_j} l_{i_j} + \left(\sum_{i=1}^k \Delta_i\right)c^\top v = c^\top p$. $\square$

Note that algorithm 3 assumes that the input point $x$ is given by its convex decomposition into vertices. All optimization algorithms in this work
use 3 in the following way: they give as input to 3 the current iterate $x_t$ and then given the output of algorithm 3 $p_t$ they produce the next iterate $x_{t+1}$ by a taking a convex combination $x_t + 1 \leftarrow (1 - \alpha)x_t + \alpha p_t$ for some parameter $\alpha \in (0, 1)$. Thus if the convex decomposition of $x_t$ is given, updating it to the convex decomposition of $x_{t+1}$ is straightforward. Moreover, denoting $\mathcal{V}_t \subseteq \mathcal{V}$ the set of vertices that form the convex decomposition of $x_t$, it is clear from algorithm 3 that $|\mathcal{V}_{t+1} \setminus \mathcal{V}_t| \leq 1$, since at most a single vertex ($v$) is added to the decomposition.

**Lemma 6.** Algorithm 3 has an implementation such that each invocation of the algorithm requires a single call to the oracle $\mathcal{O}_P$ and additional $O(T(n + \log T))$ time where $T$ is the total number of calls to algorithm 3.

**Proof.** Clearly algorithm 3 calls $\mathcal{O}_P$ only once. The complexity of all other operations depends on $k$ - the number of vertices in the convex decomposition of the input point $x$. As we discussed, if we denote by $x_t, x_{t+1}$ the inputs to the algorithm on calls number $t, t + 1$ to the algorithm and by $k_t, k_{t+1}$ the number of vertices in the convex decomposistion of $x_t, x_{t+1}$ respectively then $k_{t+1} \leq k_t + 1$. Thus if the algorithm is called a total number of $T$ times and the initial point ($x_1$) is a vertex, then at all times $k \leq T$. Since all other operations except for calling $\mathcal{O}_P$ consist of computing $k$ inner products between vectors in $\mathbb{R}^n$ and sorting $k$ scalars, the lemma follows.

Note that we can get rid of the linear dependence on $T$ in the bound in lemma 3 by decomposing the iterate $x_t$ into a convex sum of fewer vertices in case the number of vertices in the current decomposition ($k$) becomes to large. From Caratheodory’s theorem we know that there exists a decomposition with at most $n + 1$ vertices and for many polytopes of interest there is an efficient algorithm for computing such a decomposition. Another method for computing such a small decomposition is by boot-strapping algorithm 2 for solving the optimization problem $\min_{x \in \mathcal{P}} \|x_t - x\|^2$.

### 6 Online and Stochastic Convex Optimization

In this section we present algorithms for the general setting of online convex optimization that are suitable when the decision set is a polytope. We present regret bounds for both general convex losses and for strongly convex losses.

Our algorithm for online convex optimization is given below. The functions $F_t(x)$, used by the algorithm (in line 6), will be specified precisely in
the analysis. Informally, $F_t(x)$ aggregates information on the loss functions on all times $1..t$ plus some regularization term.

### Algorithm 4

1: Input: horizon $T$, learning rate $\eta > 0$, set of radii $\{r_t\}_{t=1}^T$, optimization parameter $\alpha \in (0, 1)$, LLO $A$ with parameter $\rho$.
2: Let $x_1$ be an arbitrary vertex in $\mathcal{V}$.
3: for $t = 1...T$ do
4:   play $x_t$.
5:   receive $f_t$.
6:   $p_t \leftarrow A(x_t, r_t, \nabla F_t(x_t))$.
7:   $x_{t+1} \leftarrow x_t + \alpha(p_t - x_t)$.
8: end for

We have the following two main results.

Denote $G = \sup_{x \in \mathcal{P}, t \in [T]} \|\nabla f_t(x)\|$.

**Theorem 2.** For general convex losses the regret of algorithm 4 is $O(GD\rho \sqrt{T})$.

**Theorem 3.** If all loss functions $f_t(x)$ are $H$-strongly convex then the regret of algorithm 4 is $O((G + HD^2\rho^2/H) \log T)$.

### 6.1 Analysis for general convex losses

For time $t \in [T]$ we define the function $F_t(x) = \eta \left( \sum_{\tau=1}^t \nabla f_{\tau}(x_{\tau})^\top x \right) + \|x - x_1\|^2$ where $\eta$ is a parameter that will by determined in the analysis.

Denote $x^*_1 = x_1$ and for all $t \in [T - 1]$ $x^*_{t+1} = \arg\min_{x \in \mathcal{P}} F_t(x)$. Denote also $x^* = \arg\min_{x \in \mathcal{P}} \sum_{t=1}^T f_t(x)$. Observe that $F_t(x)$ is 1-smooth and 1-strongly convex.

**Lemma 7.** There is a choice for the parameters $\eta, \alpha, r_t$ such that for any $\epsilon > 0$ it holds that for all $t \in [T]$: $\|x_t - x^*_t\| \leq \sqrt{\epsilon}$.

**Proof.** We prove by induction that for all $t \in [T]$ it holds that $F_{t-1}(x_t) - F_{t-1}(x^*_t) \leq \epsilon$. By the strong-convexity of $F_{t-1}$ this yields that $\|x_t - x^*_t\| \leq \sqrt{\epsilon}$.

The proof is by induction on $t$. For $t = 1$ it holds that $x_1 = x^*_1$ and thus the claim holds. Thus assume that for time $t \geq 1$ it holds that $F_{t-1}(x_t) - F_{t-1}(x^*_t) \leq \epsilon$. By the strong-convexity of $F_{t-1}(x)$ and the assumption that the claim holds for time $t$ we have that,

$$\|x_t - x^*_t\| \leq \sqrt{\epsilon}$$

(4)
By the definition of $F_t(x)$ and $x_t^*$ we have that $F_t(x_t^*) - F_t(x_{t+1}^*) = F_{t-1}(x_t^*) - F_{t-1}(x_{t+1}^*) + \eta \nabla f_t(x_t)(x_t^* - x_{t+1}^*) \leq \eta G \|x_{t+1}^* - x_t^*\|$ and thus again by the strong convexity of $F_t(x)$ we have that

$$
\|x_{t+1}^* - x_t^*\| \leq \eta G \tag{5}
$$

Combining (4), (5) we have,

$$
\|x_t - x_{t+1}^*\| \leq \sqrt{\epsilon} + \eta G
$$

By induction,

$$
F_t(x_t) - F_t(x_{t+1}^*) = F_{t-1}(x_t) - F_{t-1}(x_{t+1}^*) + \eta \nabla f_t(x_t)^T (x_t - x_{t+1}^*) \\
\leq \epsilon + \eta G \|x_t - x_{t+1}^*\| \leq \epsilon + \eta G \sqrt{\epsilon} + \eta^2 G^2 \tag{6}
$$

Setting $r_t = \sqrt{\epsilon} + \eta G$ we can apply lemma [1] with respect to $F_t(x)$ and get,

$$
F_t(x_{t+1}) - F_t(x_{t+1}^*) \leq (1 - \alpha)(F_t(x_t) - F_t(x_{t+1}^*)) + \alpha^2 \rho^2 (\sqrt{\epsilon} + \eta G)^2
$$

Plugging (6),

$$
F_t(x_{t+1}) - F_t(x_{t+1}^*) \leq (1 - \alpha) \left( \epsilon + \eta G \sqrt{\epsilon} + \eta^2 G^2 \right) + 2\alpha^2 \rho^2 \left( \epsilon + \eta G \sqrt{\epsilon} + \eta^2 G^2 \right)
$$

Setting $\alpha = \frac{1}{2\rho^2}$ we get,

$$
F_t(x_{t+1}) - F_t(x_{t+1}^*) \leq \left( \epsilon + \eta G \sqrt{\epsilon} + \eta^2 G^2 \right) \left( 1 - \frac{1}{9\rho^2} \right)
$$

Plugging $\eta = \frac{\sqrt{\epsilon}}{18G\rho^2}$ gives

$$
F_t(x_{t+1}) - F_t(x_{t+1}^*) \leq \epsilon \left( 1 + \frac{1}{9\rho^2} \right) \left( 1 - \frac{1}{9\rho^2} \right) < \epsilon
$$

we are now ready to prove theorem [2]

Proof. Observe that playing the point $x_{t+1}^* = \arg\min_{x \in P} F_t(x)$ on each time $t$ is equivalent to playing the leader on each time with respect to the loss functions $f_t(x) = \nabla f_t(x)^T x + \frac{1}{\eta} \|x - x_1\|^2$ and $f_t'(x) = \nabla f_t(x)^T x$ for every $t > 1$. This strategy of playing on each time according to the leader is known to achieve overall zero regret, see [13]. Thus,

$$
\sum_{t=1}^{T} \nabla f_t(x_t)^T (x_{t+1}^* - x_t^*) \leq \frac{1}{\eta} (\|x^* - x_1\|^2 - \|x_{t+1}^* - x_t\|^2) \leq \frac{D^2}{\eta}
$$
By the definition of $F_t(x)$, $x^*_t$ and the use of strong-convexity we have that,

$$
\|x^*_t - x^*_t + 1\|_2^2 \leq F_t(x^*_t) - F_t(x^*_t + 1) \leq \eta G \|x^*_t - x^*_t + 1\|
$$

Which implies by the triangle inequality that,

$$
\sum_{t=1}^{T} \nabla f_t(x_t)^\top (x^*_t - x^*_t + 1) \leq \frac{D^2}{\eta} + T\eta G^2
$$

Setting $\eta$ to the value determined in lemma [7], plugging lemma [7] and by the convexity of $f_t()$ we get that for all $\epsilon > 0$,

$$
\sum_{t=1}^{T} f_t(x_t) - f_t(x^*_t) \leq \sum_{t=1}^{T} \nabla f_t(x_t)^\top (x_t - x^*_t) \leq \frac{18GD^2\rho^2}{\sqrt{\epsilon}} + \frac{T G \sqrt{\epsilon}}{18\rho^2} + TG \sqrt{\epsilon}
$$

The theorem now follows from plugging $\epsilon = \frac{(D\rho)^2}{T}$.

### 6.2 Analysis for strongly convex losses

Assume all loss functions are $H$-strongly-convex. For time $t \in [T]$ define $\tilde{f}_t(x) = \nabla f_t(x_t)^\top x + H \|x - x_t\|^2$ and $F_t(x) = \left( \sum_{t=1}^{T} \tilde{f}_t(x) \right) + HT_0 \|x - x_1\|^2$ for some constant $T_0$ that will be determined later. Observe that $F_t(x)$ is $H(t + T_0)$-smooth and $H(t + T_0)$-strongly convex.

Denote $L = G + 2HD$.

**Claim 2.** For all $t \in [T]$, $\tilde{f}_t(x)$ is $L$-Lipschitz over $\mathcal{P}$.

**Proof.** Given two points $x, y \in \mathcal{P}$ it holds that

$$
\tilde{f}_t(x) - \tilde{f}_t(y) = \nabla f_t(x_t)^\top (x - y) + H \|x - x_t\|^2 - H \|y - x_t\|^2 \leq G \|x - y\| + H \left( \|x - x_t\|^2 - \|y - x_t\|^2 \right)
$$

Using the convexity of the function $g(x) = \|x - x_t\|^2$ we have,

$$
f_t(x) - f_t(y) \leq G \|x - y\| + 2H(x - x_t)^\top (x - y) \leq G \|x - y\| + 2HD \|x - y\|
$$

The same argument clearly holds for $\tilde{f}_t(y) - \tilde{f}_t(x)$ and thus the claim follows.

**Lemma 8.** There is a choice for the parameters $\alpha, r_t, T_0$ such that for any $t \in [T]$ it holds that $\|x_t - x^*_t\| \leq \frac{100\rho^2 L}{Ht}$.
Proof. The proof is similar to that of lemma 7. We prove that for any time \( t \in [T], F_{t-1}(x_t) - F_{t-1}(x_t^*) \leq \epsilon_t \) for some \( \epsilon_t > 0 \) which by strong convexity implies that \( \|x_t - x_t^*\| \leq \sqrt{\epsilon_t H(t-1+T_0)}. \)

Clearly for time \( t = 1 \) the claim holds since \( x_1 = x_1^* \). Assume that on time \( t \) it holds that \( F_{t-1}(x_t^*) - F_{t-1}(x_t) \leq \epsilon_t \). Thus as we have shown,

\[
\|x_t^* - x_t\| \leq \sqrt{\frac{\epsilon_t}{H(t-1+T_0)}},
\]

(7)

It also holds that \( F_t(x_t^*) - F_t(x_{t+1}^*) = F_{t-1}(x_t^*) - F_{t-1}(x_{t+1}^*) + \tilde{f}_t(x_t^*) - \tilde{f}_t(x_{t+1}^*). \) By claim 2 we thus have that \( F_t(x_t^*) - F_t(x_{t+1}^*) \leq L\|x_t^* - x_{t+1}^*\|. \) By strong-convexity of \( F_t(x) \) we have,

\[
\|x_{t+1}^* - x_t^*\| \leq \frac{L}{H(t+T_0)}
\]

(8)

Combining (7), (8) we have,

\[
\|x_t - x_{t+1}^*\| \leq \sqrt{\frac{\epsilon_t}{H(t-1+T_0)}} + \frac{L}{H(t+T_0)}
\]

(9)

By induction and claim 2

\[
F_t(x_t) - F_t(x_{t+1}^*) = F_{t-1}(x_t) - F_{t-1}(x_{t+1}^*) + \tilde{f}_t(x_t) - \tilde{f}_t(x_{t+1}^*)
\]

\[
\leq \epsilon_t + \frac{L}{\sqrt{H(t-1+T_0)}} + \frac{L^2}{H(t+T_0)}
\]

Setting \( \epsilon_t \) to the bound in (9), applying lemma 4 with respect to \( F_t(x) \) we have,

\[
F_t(x_{t+1}) - F_t(x_{t+1}^*) \leq (1 - \alpha)(F_t(x_t) - F_t(x_{t+1}^*)) + H(t + T_0)\alpha^2 \rho^2 \epsilon_t^2
\]

\[
\leq (1 - \alpha) \left( \epsilon_t + \frac{L^2}{\sqrt{H(t-1+T_0)}} + \frac{L^2}{H(t+T_0)} \right)
\]

\[
+ 2H(t + T_0)\alpha^2 \rho^2 \left( \epsilon_t + \frac{L^2}{H(t-1+T_0)} \right)
\]

\[
\leq (1 - \alpha) \left( \epsilon_t + \frac{L^2}{\sqrt{H(t-1+T_0)}} + \frac{L^2}{H(t+T_0)} \right)
\]

\[
+ \frac{2H(t + T_0)\alpha^2 \rho^2}{H(t-1+T_0)} \left( \epsilon_t + \frac{L^2}{H(t+T_0)} \right)
\]

\[
\leq \left( \epsilon_t + \frac{L}{\sqrt{H(t-1+T_0)}} \right) \left( \epsilon_t + \frac{L^2}{H(t+T_0)} \right) \left( 1 - \alpha + 4\alpha^2 \rho^2 \right)
\]

19
Setting $α = \frac{1}{5ρ^2}$ we get,

$$F_t(x_{t+1}) - F_t(x^*_{t+1}) \leq \left( ϵ_t + \frac{L\sqrt{c_t}}{H(t-1+T_0)} + \frac{L^2}{H(t+T_0)} \right) \left( 1 - \frac{1}{25ρ^2} \right)$$

Assume now that $ϵ_t \leq \frac{(100ρ^2L)^2}{H(t+T_0)}$. Then we have,

$$F_t(x_{t+1}) - F_t(x^*_{t+1}) \leq \frac{(100ρ^2L)^2}{H(t+T_0)} \left( 1 + \frac{1}{50ρ^2} + \frac{1}{(50ρ^2)^2} \right) \left( 1 - \frac{1}{25ρ^2} \right)$$

$$= \frac{(100ρ^2L)^2}{H(t+T_0)} \left( 1 - \frac{1}{(25ρ^2)^2} \right)$$

Finally, setting $T_0 = (25ρ^2)^2$ we have that,

$$F_t(x_{t+1}) - F_t(x^*_{t+1}) \leq \frac{(100ρ^2L)^2}{H(t+T_0)} \left( 1 - \frac{1}{T_0} \right) \leq \frac{(100ρ^2L)^2}{H(t+T_0)} \left( 1 - \frac{1}{t+1+T_0} \right)$$

$$= \frac{(100ρ^2L)^2}{H(t+T_0)} \cdot \frac{t+T_0}{t+1+T_0} = \frac{(100ρ^2L)^2}{H(t+1+T_0)}$$

Thus for all $t$, $F_t(x_{t+1}) - F_t(x^*_{t+1}) \leq \frac{(100ρ^2L)^2}{H(t+(25ρ^2)^2)}$, and the lemma follows. □

We are now ready to prove theorem 3.

Proof. Following the lines of theorem 2 and noticing that on time $t$, $x^*_{t+1}$ is the leader with respect to the loss functions $f'_t(x) = \tilde{f}_t(x) + HT_0\|x - x_1\|^2$ and $f'_t(x) = \tilde{f}_t(x)$ for all $t > 1$ we have that,

$$\sum_{t=1}^{T} \tilde{f}_t(x^*_{t+1}) - \tilde{f}_t(x^*) \leq HT_0(\|x^* - x_1\|^2 - \|x^*_{t+1} - x_1\|^2) \leq HT_0D^2$$

By the definition of $F_t(x)$, $x^*_t$, the use of strong-convexity and claim 2 we have that,

$$Ht\|x^*_t - x^*_{t+1}\|^2 \leq H(t+T_0)\|x^*_t - x^*_t\|^2 \leq F_t(x^*_t) - F_t(x^*_{t+1})$$

$$= \tilde{f}_t(x^*_{t+1}) - \tilde{f}_t(x^*_t) \leq L\|x^*_{t+1} - x^*_t\|$$

20
Which implies that,
\[
\sum_{t=1}^{T} \tilde{f}_t(x_t) - \tilde{f}_t(x^*) = \sum_{t=1}^{T} \tilde{f}_t(x_t) - \tilde{f}_t(x^*) + \tilde{f}_t(x_{t+1}^*) - \tilde{f}_t(x_{t+1}^*)
\]
\[
\leq \sum_{t=1}^{T} \tilde{f}_t(x_{t+1}^*) - \tilde{f}_t(x^*) + \sum_{t=1}^{T} \tilde{f}_t(x_t) - \tilde{f}_t(x_{t+1}^*)
\]
\[
\leq HT_0D^2 + \sum_{t=1}^{T} \tilde{f}_t(x_t) - \tilde{f}_t(x_{t+1}^*) + \sum_{t=1}^{T} \tilde{f}_t(x_{t+1}^*) - \tilde{f}_t(x_{t+1}^*)
\]
\[
\leq HT_0D^2 + \sum_{t=1}^{T} L (\|x_t - x_t^*\| + \|x_{t+1}^* - x_{t+1}\|)
\]
\[
\leq HT_0D^2 + \sum_{t=1}^{T} L \left(\|x_t - x_t^*\| + \frac{L}{Ht}\right)
\]

Plugging the value of $T_0$ chosen in lemma 8 and the result of lemma 8 we have,
\[
\sum_{t=1}^{T} \tilde{f}_t(x_t) - \tilde{f}_t(x^*) \leq O(HD^2\rho^4) + 2 \sum_{t=1}^{T} \frac{100\rho^2L^2}{Ht} = O\left(\frac{\rho^2L^2}{H} \log T\right)
\]

The theorem follows from the observation that for all $t$, since $f_t(x)$ is $H$-strongly convex it holds that,
\[
f_t(x_t) - f_t(x^*) \leq \nabla f_t(x_t)^\top (x_t - x^*) - H\|x_t - x^*\|^2
\]
\[
= \nabla f_t(x_t)^\top (x_t - x^*) - H((\|x_t - x^*\|^2 - \|x_t - x_t\|^2)
\]
\[
= \tilde{f}_t(x_t) - \tilde{f}_t(x^*)
\]
